Outline

A general process of scientific investigation

Descriptive statistics

Case study

General Process of Scientific Investigation

1. Identify a question or problem.

2. Collect relevant data on the topic.

3. Analyze the data.

4. Form a conclusion.

Identify Research Question/Problem

What?

Why?

How?

When?

Question to keep in mind

Is there uncertain in the data generation process? Where does the uncertainty (variation) come from?

- Sample → Population

- Unobserved factors

- Chance

- Measurement error

Data Collection

Observational study data are collected in a way that does not directly interfere with how the data arise. In general, observational studies can provide evidence of a naturally occurring association between variables, but they cannot by themselves show a causal connection.

Experiments: a sample of individuals are randomly assigned into control or treatment groups. Randomized experiments may be used to establish causality.

Methods of sampling

Almost all statistical methods are based on the notion of implied randomness.

If observational data are not collected in a random framework from a population, these statistical methods -- the estimates and errors associated with the estimates -- are not reliable.

Most commonly used random sampling techniques are simple, stratified, and cluster sampling.
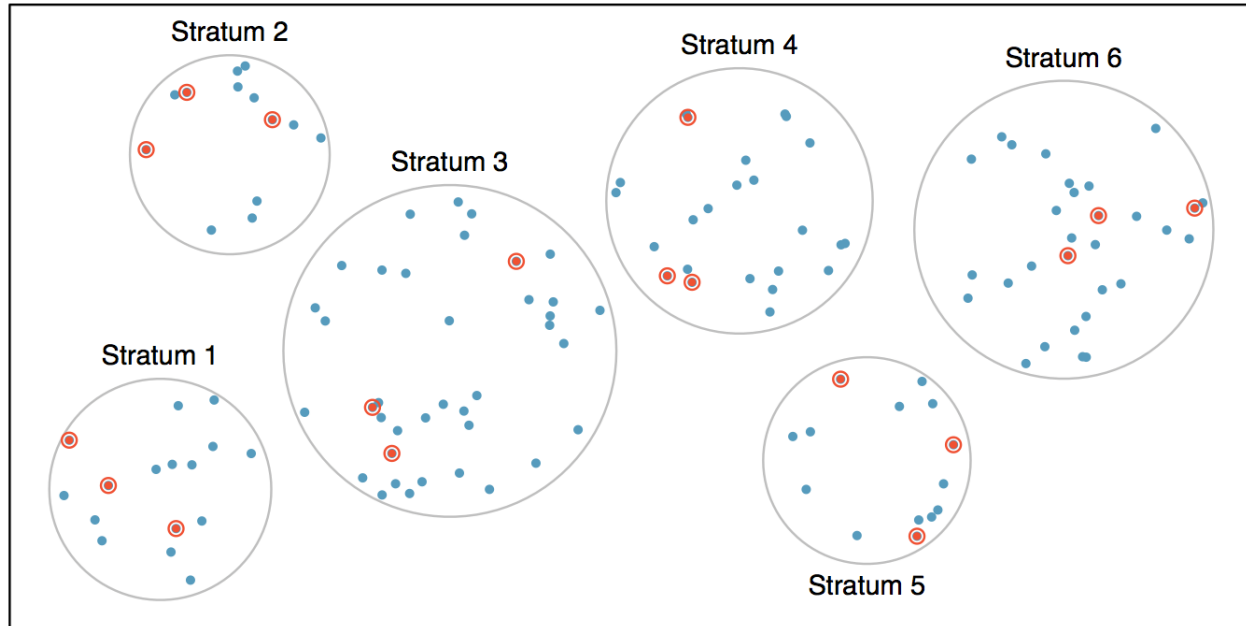

Simple Random Sample

Randomly select cases from the population, where there is no implied connection between the points that are selected.
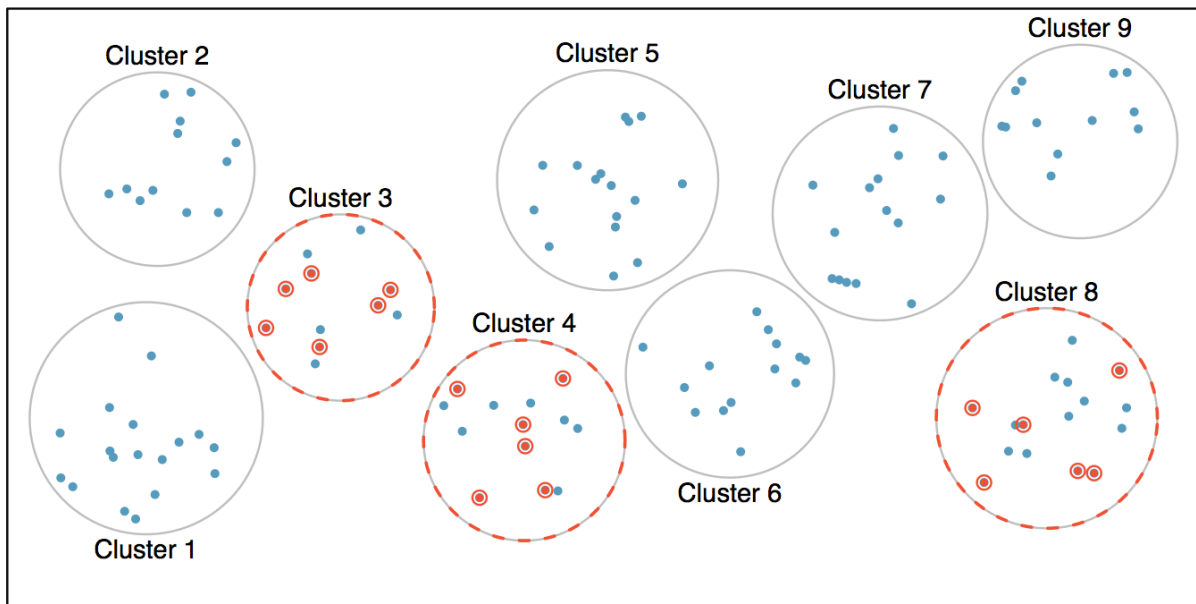

Stratified Sample

Strata are made up of similar observations. We take a simple random sample from each stratum.

Cluster Sample

Clusters are usually not made up of homogeneous observations, and we take a simple random sample from a random sample of clusters. Usually preferred for economical reasons.

Sampling bias

Non-response: If only a small fraction of the randomly sampled people choose to respond to a survey, the sample may no longer be representative of the population.

Voluntary response: Occurs when the sample consists of people who volunteer to respond because they have strong opinions on the issue. Such a sample will also not be representative of the population.

Convenience sample: Individuals who are easily accessible are more likely to be included in the sample.

Types of variables
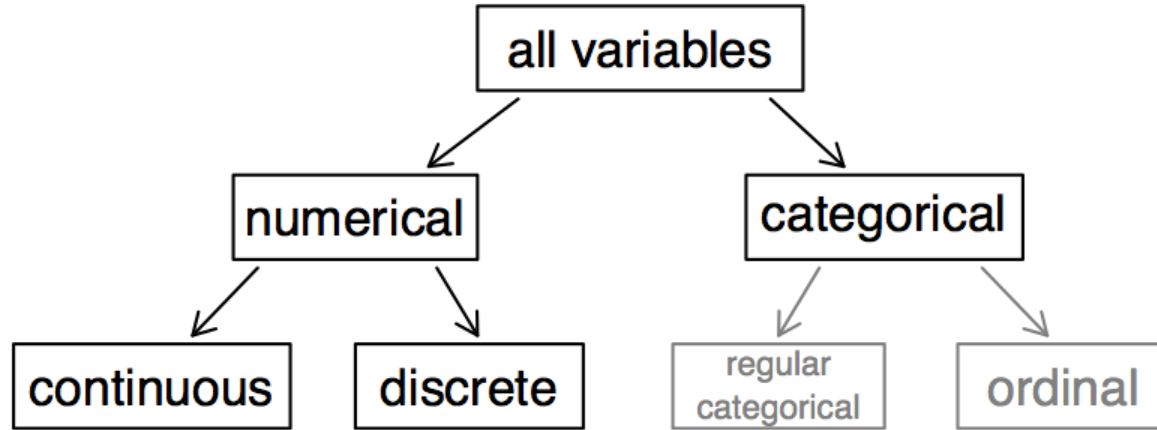

Analyze Data: Descriptive Statistics

Descriptive Statistics quantitatively describes the features of a data set. Descriptive statistics are distinguished from **inferential statistics**, in that descriptive statistics aim to summarize a sample, rather than use the data to generalize information about the population.

Analyze Data: Descriptive Statistics

One continuous variable

Quantitative: mean, sd, median, range, IQR; skewness, Kurtosis

Visualization: Histogram, box plot, density plot

One Categorical variable

Quantitative: Frequency table, mode, *mean* (ordinal)

Visualization: Bar chart, bar chart

Two continuous variables (X → Y):

Quantitative: measure of correlation (e.g. Pearson's R)

Visualization: Scatter Plot

Scatter plots

Scatter plots have two dimensions:

The independent variable (X) is plotted along the horizontal axis (which is called "the X axis").

The dependent variable (Y) is plotted along the vertical axis (which is called "the Y axis").
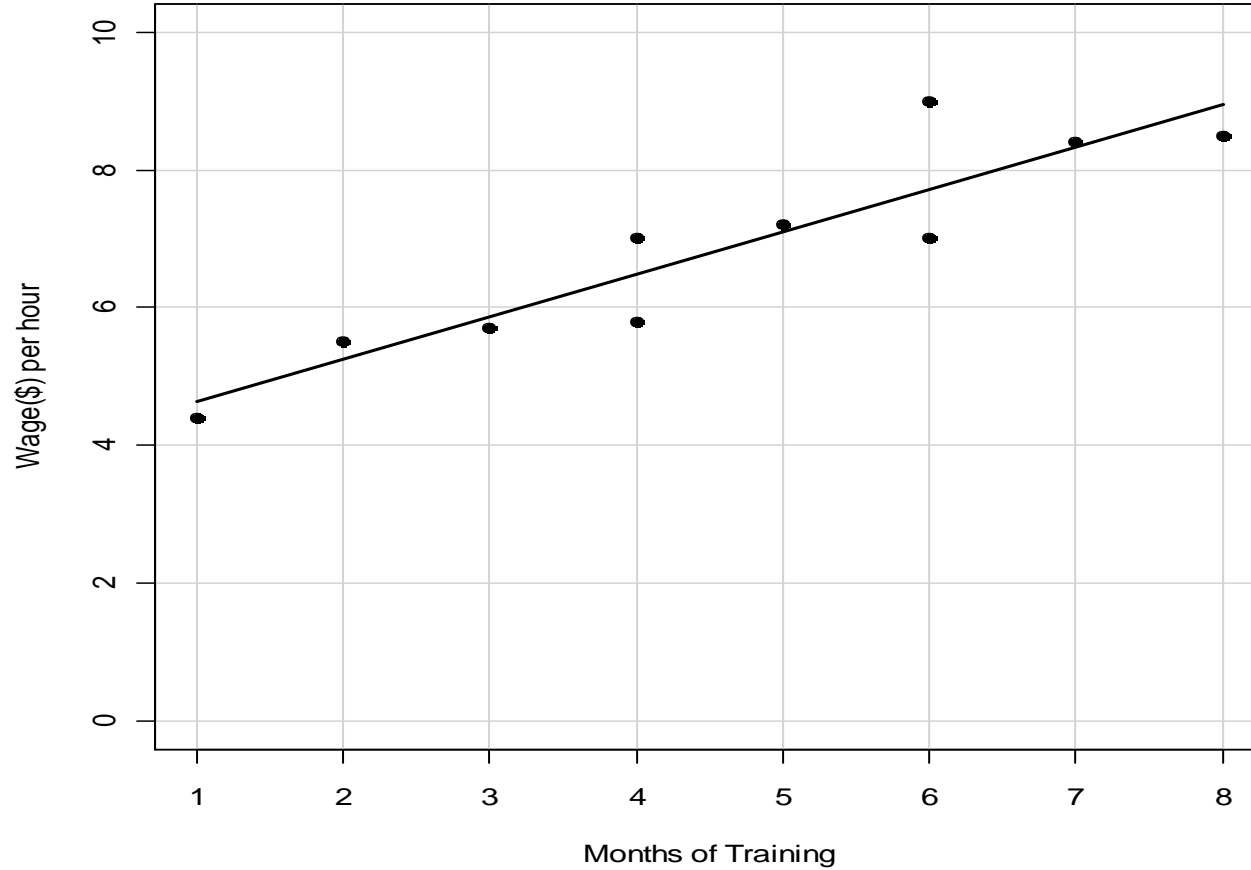

Each dot on a scatter plot is a case/an observation.

The dot is placed at the intersection of the case's scores on X and Y.

Scatter Plot of Wage v.s. Months of Training

Wage($) per hour
Months of Training

X	Y
1	4.4
2	5.5
3	5.7
4	5.8
4	7
5	7.2
6	7
6	9
7	8.4
8	8.5

Scatter Plot of Wage v.s. Months of Training

6	9
7	8.4
8	8.5

Regression line: Strength and direction

Strength of association

The greater the extent to which dots are clustered around the regression line, the stronger the relationship

Direction of association

Positive: regression line rises left to right.

Negative: regression line falls left to right.

Slope of regression line

Steeper slope implies larger "effect"—but caution: this partly an artifact of variable *units* and outliers

How do we measure the association of X and Y?

Use a calculated regression line, if linear relationship is appropriate

Another way to measure the extent of clustering around the regression line is to using Pearson's r or R^2. These measures can be tested for statistical significance.

Pearson's r

AKA Pearson Product-Moment **Correlation**

Pearson's r is a measure of association for numeric variables:

$$r = \frac{\sum(X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum(X_i - \bar{X})^2}\sqrt{\sum(Y_i - \bar{Y})^2}}$$
Ranges from -1 to 1:

- 0 indicates no relationship,

- -1 a perfect negative relationship

- 1 a perfect positive relationship

Limitation: No direct interpretation of intermediate values

Correlation: Pearson's r

R code: `cor(X,Y)`

-1   0   .916   1

| N = 10 |
| $\Sigma X_i = 46$ |
| $\Sigma X_i^2 = 256$ |
| $\Sigma Y_i = 68.5$ |
| $\Sigma Y_i^2 = 489.4$ |
| $\Sigma X_i Y_i = 342.5$ |
| $\bar{X} = 4.60$ |
| $\bar{Y} = 6.85$ |

X	Y
1	4.4
2	5.5
3	5.7
4	5.8
4	7
5	7.2
6	7
6	9
7	8.4
8	8.5

Correlation

Assume a linear relationship

Sensitive to outliers

Always look at scatter plot, not just r statistic.
Four sets of data with the same correlation of 0.816

One categorical (explanatory) and one continuous (response) variables:

Quantitative: measure of correlation (e.g. Pearson's R)

Visualization: grouped box plot, scatter plot, line chart, bar chart

One Continuous (explanatory) and One categorical (response) variables:

Quantitative: measure of correlation (e.g. Pearson's R)

Visualization: (jittered) scatter Plot

Two categorical variables:

Quantitative: contingency table (cross tabulation), measure of correlation

Visualization: stacked bar chart, mosaic plot

Time Series: Continuous Variable

Case Study: Gender Discrimination

Gender Discrimination

- In 1972, as a part of a study on gender discrimination, 48 male bank supervisors were each given the same personnel file and asked to judge whether the person should be promoted to a branch manager job that was described as "routine".
- The files were identical except that half of the supervisors had files showing the person was male while the other half had files showing the person was female.
- It was randomly determined which supervisors got "male" applications and which got "female" applications.
- Of the 48 files reviewed, 35 were promoted.
- The study is testing whether females are unfairly discriminated against.

Is this an observational study or an experiment?

Experiment

B.Rosen and T. Jerdee (1974), ``Influence of sex role stereotypes on personnel decisions", J.Applied Psychology, 59:9-14.

Data

At a first glance, does there appear to be a relationship between promotion and gender?

		Promotion		
		Promoted	Not Promoted	Total
Gender	Male	21	3	24
	Female	14	10	24
	Total	35	13	48

% of males promoted: 21 / 24 = 0.875

% of females promoted: 14 / 24 = 0.583

Practice

We saw a difference of almost 30% (29.2% to be exact) between the proportion of male and female files that are promoted. Based on this information, which of the below is true?

(a) If we were to repeat the experiment we will definitely see that more female files get promoted. This was a fluke.

(b) Promotion is dependent on gender, males are more likely to be promoted, and hence there is gender discrimination against women in promotion decisions.

(c) The difference in the proportions of promoted male and female files is due to chance, this is not evidence of gender discrimination against women in promotion decisions.

(d) Women are less qualified than men, and this is why fewer females get promoted.

Practice

We saw a difference of almost 30% (29.2% to be exact) between the proportion of male and female files that are promoted. Based on this information, which of the below is true?

(a) If we were to repeat the experiment we will definitely see that more female files get promoted. This was a fluke.

(b) *Promotion is dependent on gender, males are more likely to be promoted, and hence there is gender discrimination against women in promotion decisions.* *Maybe*

(c) *The difference in the proportions of promoted male and female files is due to chance, this is not evidence of gender discrimination against women in promotion decisions.* *Maybe*

(d) Women are less qualified than men, and this is why fewer females get promoted.

Two Competing Claims

"There is nothing going on." (Null Hypothesis)

Promotion and gender are independent.

No gender discrimination.

Observed difference in proportions is simply due to chance.

"There is something going on." (Alternative Hypothesis)

Promotion and gender are dependent.

There is gender discrimination.

Observed difference in proportions is not due to chance.
